# How Do Households Set Prices? Evidence from Airbnb* 

Barbara Bliss $\dagger$ Joseph Engelberg ${ }^{\ddagger}$, and Mitch Warachka ${ }^{\S}$

July 2017

#### Abstract

We find Airbnb hosts in college towns increase their listing prices more than hotels on games against rival football teams. These high listing prices lower the rental incomes of Airbnb hosts, indicating that household financial decisions are influenced by non-pecuniary preferences. In particular, preferences regarding college team affiliations confound the listing prices set by households. However, financial constraints mitigate these non-pecuniary preferences.

[^0]The "sharing economy" allows households to monetize idle assets. Whether its their house (Airbnb.com), backyard (Dogvacay.com), car (Getaround.com) or spare cash (Prosper.com), households are deploying - many for the first time - assets for the purpose of generating income. According to Pricewaterhouse Coopers, the international sharing economy totaled $\$ 15$ billion in online transactions in 2014 and is on track to reach $\$ 335$ billion by 2025. ${ }^{1}$ The sharing economy requires households to make an important financial decision: how to set prices on their income-generating assets?

The behavioral finance literature has revealed a myriad of peculiarities that confound investment decisions (Hirshleifer, 2001). While internal and external governance mechanisms in corporations mitigate idiosyncratic non-pecuniary preferences, these mechanisms are not available to constrain household preferences. Therefore, the prices set by households may be sensitive to idiosyncratic non-pecuniary preferences. The purpose of this paper is to study the listing prices set by households on Airbnb to ascertain whether non-pecuniary preferences confound their financial decisions.

Airbnb is an online marketplace that enables households to rent accommodation at their specified listing price. The Airbnb listing prices set by households in college towns on home football games offer several advantages when studying household financial decisions. ${ }^{2}$ First, football rivalries evoke strong emotions, which provides an ideal laboratory to study non-pecuniary household preferences. Cikara, Botvinick, Fiske (2011) find that "us versus them" behavior spreads beyond competitors to fans. Second, we observe hotel prices in each college town on the same day as the Airbnb listing prices set by households. Thus, we can compare the price-setting of households to benchmark hotel prices. Third, we observe listing prices on Airbnb set by the same household on different home games, enabling us to observe the same household's listing price and rental income on home games against rival teams (e.g., University of Florida at Florida State) and on home games against non-rival teams (e.g., Notre Dame at Florida State). This allows us to hold the household fixed and vary their preference toward the visiting team.

Our data consist of 1,321 entire units on Airbnb in 26 college towns encompassing 232 games during the 2014-2015 football season. Entire units resemble hotel rooms, and provide self-contained accommodation. Thus, interactions between Airbnb hosts and guests typically involve no reciprocity nor personal contact since guests and hosts are physically separated. College football games are an important determinant of an Airbnb host's rental income in our sample of college towns. Over $60 \%$ of the total rental income earned by Airbnb hosts during

[^1]the football season occurs on six home-game weekends (Friday and Saturday nights). For each home game, we create a rival indicator variable that equals one for each game against a "rival" visiting team. Appendix A summarizes the college football rivalries in our study. This list of rivals is obtained from the sports media (e.g., ESPN and Sports Illustrated) and include wellknown examples such as Florida-Florida State, Notre Dame-USC, Ohio State-Michigan, and Alabama-LSU.

After controlling for unit-level heterogeneity and demand using hotel prices, we find that Airbnb hosts set higher listing prices on games against rival teams. Nearly two thirds of units have higher listing prices on games against rivals, with an average increase of $22 \%$. As listing prices reflect demand, there exists a positive unconditional relation between the listing price and rental income of individual units. However, the interaction between unit-level listing prices and the rival indicator variable exerts a negative impact on rental incomes. Consequently, the high listing prices set by households on games against rivals are suboptimal as they result in lower rental incomes.

As an illustration, Florida State had home games in Tallahassee against Notre Dame and the University of Florida during the 2014 college football season. For the home game against the fifth ranked Notre Dame, Airbnb units in Tallahassee were listed for an average listing price of $\$ 201$. As each unit was booked for this game, average rental income was also $\$ 201$. However, five weeks later, on the home game against the unranked University of Florida team, which is a rival of Florida State, the average listing price in Tallahassee was increased to $\$ 267$ but average rental income declined to $\$ 67$. In general, for every dollar in rental income earned by Airbnb hosts on highly ranked non-rival games, only $\$ 0.71$ is earned on games against rivals. For comparison, hotels obtain $\$ 0.96$ in revenue on games against rivals for every dollar in revenue on highly ranked non-rival games.

Figure 1 illustrates the listing price increases for Airbnb units relative to hotel room prices on games against rivals. This figure also illustrates that hotel prices increase more than Airbnb listing prices on homecoming, which corresponds to a large influx of home team fans (Alumni), and on other home games against non-rival visiting teams. In contrast to games against rivals, Airbnb listing prices on homecoming do not have an inverse relation with rental incomes.

The low occupancy rate of Airbnb hosts on games against rivals can be explained by hotel rooms and entire units listed on Airbnb being substitutes in conjunction with an occupancy rate below $100 \%$ for hotels. For emphasis, nearly all the Airbnb units in our sample are available for immediate booking using Airbnb's Instant Book feature. Therefore, the low occupancy rate of Airbnb hosts on games against rivals is not due to guests being denied accommodation by hosts. Instead, hosts use the price mechanism to express their preference against rival fans.

We classify hosts with more than one Airbnb listing as a professional. As with hotels, we
find no evidence of an inverse relation between listing prices and rental incomes for professional hosts on games against rivals. Additional tests condition on unit and host characteristics to confirm that the inverse relation between listing prices and rental incomes on games against rivals is difficult to attribute to the overestimation of demand. Indeed, Airbnb hosts have several months to lower their listing price to obtain a successful booking before each home game.

In contrast to entire units, shared units on Airbnb have common facilities (bathroom, kitchen, etc) and are suitable for visiting fans of the home team. We find that hosts of shared units do not increase their listing prices on games against rivals. This finding is consistent with Airbnb hosts having a preference against fans of the rival team but is inconsistent with hosts overestimating demand. Intuitively, Airbnb hosts infer whether prospective gusts are fans of the rival team or home team based on their choice of accommodation.

A further analysis reveals that the financial constraints of hosts influence listing prices. We divide the zip codes within each college town into areas whose average credit utilization score is either above or below the median credit utilization score of the respective college town. Zip codes whose average credit utilization score is above the college town's median are classified as having financially constrained hosts, while zip codes whose average credit utilization is below this median are classified as having financially unconstrained hosts. ${ }^{3}$

On games against rivals, the listing prices of financially unconstrained hosts are nearly $60 \%$ higher than those of financially constrained hosts. As a consequence of setting less competitive (higher) listing prices, financially unconstrained hosts earn less rental income on games against rivals. As financially constrained hosts do not require a large price premium to overcome their preference against rival fans, their rental incomes do not decrease on games against rival teams. ${ }^{4}$ To clarify, our empirical analysis controls for the possibility that financially unconstrained hosts have higher quality units with higher listing prices.

To illustrate the economic implications of financial constraints, financially unconstrained hosts and financially constrained hosts earn similar rental income; averaging $\$ 189$ and $\$ 187$, respectively, on games against highly ranked non-rival visiting teams. However, on games against rivals, the average rental income of financially unconstrained hosts declines by over $20 \%$ to $\$ 149$, while the average for financially constrained hosts is unchanged at $\$ 183$. Therefore, financial constraints improve the financial decisions of households with respect to setting listing prices.

Overall, suboptimal pricing on games against rival fans is limited to non-professional financially unconstrained hosts. ${ }^{5}$ These host characteristics are difficult to reconcile with the overes-

[^2]timation of demand. Instead, preferences regarding college football team affiliations appear to cause a subset of hosts to set uncompetitive listing prices. This subset is economically significant since $40 \%$ of the entire units listed on Airbnb have non-professional financially unconstrained hosts.

To clarify, the cost of providing accommodation to rival fans is not higher because of their higher propensity to cause damage. The probability a unit sustains damage is unrelated to the financial constraints of its host. Moreover, hotel prices are not higher on games against rivals despite hotel rooms also being susceptible to damage. Furthermore, Airbnb hosts do not require higher damage deposits on games against rivals, nor are hosts more likely to block their units from being rented on games against rivals. Airbnb also insures hosts for a million dollars in property damage. ${ }^{6}$ Finally, the probability that units booked on games against rivals subsequently become unavailable for rent is not higher than for units booked on games against non-rivals. Thus, providing accommodation to rival fans is not associated with damage that prevents subsequent rental income.

A placebo test attempts to replicate our results in urban areas such as Los Angeles that have more than 1,000 Airbnb listings. Consistent with college football games representing a less salient increase in the demand for accommodation in urban areas, we find no inverse relation between listing prices and rental incomes in urban areas on games against rivals.

The growing importance of the sharing economy to household finances is increasingly attracting the attention of academics. Duarte, Siegel, and Young (2012) as well as Iyer, Khwaja, Luttmer, and Shue (2015) examining online peer-to-peer lending markets. In contrast to lenders, Airbnb hosts are sellers whose pricing power derives from the uniqueness of their rental properties. Thus, Airbnb hosts have more discretion when setting listing prices than lenders setting interest rates. Moreover, the demand for Airbnb accommodation is concentrated on a few home games, while lenders have multiple opportunities to deploy their savings.

## 1 Data

Our analysis uses Airbnb data for units near college football stadiums. A guest can book a unit on Aribnb at the listing prices specified by the host on specific dates. Airbnb receives a $3 \%$ fee from the host for each completed booking and an additional service fee from guests. In our sample of college towns, Airbnb earnings are concentrated on home games where guests typically book two to three nights of accommodation. Figure 2 illustrates the importance of weekends to Airbnb hosts, whose units have a lower occupancy than hotels on weekdays.

[^3]Variation in listing prices during the football season is dramatic for Airbnb units located in college towns since home games represent large anticipated increases in demand for accommodation. We examine units whose listing price changes at least once during the football season to ensure the Airbnb hosts in our sample are active. Initially, we focus on entire units that resemble large hotel rooms with self-contained facilities. Entire units are appropriate for rival fans who prefer being physically separate from fans of the home team. A later empirical test examines shared units on Airbnb.

We identify the top 30 ranked college football programs for the 2014 and 2015 football seasons. The teams include Arizona State University, University of Alabama, University of Arkansas, Auburn University, University of California-Los Angeles, Clemson University, University of Florida, Florida State University, University of Georgia, University of Iowa, University of Kentucky, Louisiana State University, University of Michigan, Michigan State University, Mississippi State University, University of Nebraska, University of Notre Dame, Ohio State University, University of Oklahoma, University of Oregon, Oregon State University, Stanford University, University of Southern California, University of South Carolina, Texas Christian University, University of Tennessee, University of Texas, Texas Tech University, University of Utah, and University of Wisconsin.

We limit our main analysis to college towns with fewer than 1,000 entire unit listings on Airbnb per football season to exclude teams in urban areas such as Los Angeles (teams excluded: USC, UCLA, Stanford, and Texas). Urban areas are examined separately in a later placebo test. We also restrict our sample of Airbnb listings to units located within 15 miles from the stadium.

Next, we identify pairs of rivals and require at least 50 prior games between these teams. If a team does not have at least one home game against a rival, the team's entire season is eliminated from the sample. Our final sample consists for 232 unique home games that contain 42 games against a rival. Appendix A contains a complete list of rivals. We identify two determinants of a college football rivalry. Rival teams have played each other for many years and have a wonloss record near parity. As the first game between rivals often occurred before long-distance travel was made convenient by interstate highways and aviation, rivals are often located in the same state or contiguous states. However, most college football fans do not reside in college towns since Alumni leave college towns upon graduation. Consequently, our empirical results are robust to controlling for the distance between college football stadiums.

A unit-level Airbnb Listing Premium is calculated as the listing price on a specific game minus the unit's average listing price across all home games. Our results are similar using alternative benchmarks such as the average listing price for all home games against non-rival teams. Besides Airbnb data, our study utilizes average hotel prices, occupancy rates, and income from STR, formerly known as Smith Travel Research, within a 15 mile radius of each college
football stadium. As with the Airbnb Listing Premium, Hotel Listing Premium is computed as the average hotel price on a specific game minus the average hotel price across all home games.

Table 1 reports the average number of units listed, listing price, rental income, listing premium, and occupancy rate on different home games for Airbnb units. In addition, the average listing price, rental income, listing premium, and occupancy rate of hotels are also reported. Observe that the average listing price of $\$ 277.06$ on Airbnb is highest on games against rival visiting teams, which corresponds to the highest Airbnb listing premium of $\$ 28.77$ but the lowest occupancy of $65.03 \%$. Indeed, games against rivals fail to generate the highest average rental income due to this low occupancy rate. ${ }^{7}$ In contrast to Airbnb units, hotel prices are not highest on games against rivals.

Table 1 also indicates that the supply of entire units listed on Airbnb is stable across different home games. Consequently, lower rental income on games against rivals cannot be attributed to an increased supply of Airbnb units.

## 2 Empirical Results

Our empirical tests examine unit-level listing prices, occupancy rates, and rental incomes. Using zip code level data, we then incorporate the financial constraints of hosts into our analysis.

### 2.1 Listing Prices

The high average listing premium on games against rivals in Table 1 motivates an analysis of listing premiums using the following panel regression

$$
\begin{equation*}
\text { Airbnb Listing Premium }_{i, t}=\beta_{1} \operatorname{Rival}_{i, t}+\gamma X_{t}+\epsilon_{i, t} \tag{1}
\end{equation*}
$$

with unit fixed effects that control for the each unit's quality, including its location (distance to the stadium). Standard errors are clustered at the team level. The $\beta_{1}$ coefficient in this specification determines whether games against rivals are associated with a larger listing premiums after controlling for a multitude of demand proxies.

The demand proxies include indicator variables for games during prime time and on homecoming weekend. The rank of the home team and the visiting team before the game are also included, along with an indicator variable for whether the opponent was highly ranked before the football season. Most important, Hotel Listing Premium proxies for demand on each home

[^4]game, while the number of entire units listed on Airbnb accounts for the supply of Airbnb accommodation. A full list of variable definitions is contained in Appendix C.

The positive $\beta_{1}$ coefficients in Panel A of Table 2 indicate that Airbnb hosts increase their listing prices on games against rivals. For example, the 24.756 coefficient ( $t$-statistic of 5.982) in the last specification with all control variables indicates that listing prices are nearly $\$ 25$ higher on games against rivals compared to the average home game. Thus, after controlling for multiple demand proxies, including hotel prices, we find that games against rivals are associated with higher Airbnb listing prices.

The positive coefficients for Hotel Listing Premium indicate that Airbnb listing prices comove with hotel prices. This finding is consistent with hotel rooms and entire units on Airbnb being substitutes. The negative coefficients for the Prime Time Game indicator variable are at odds with the positive coefficients in Panel B for hotels. Intuitively, prime time games are more important, and therefore increase Airbnb listing prices. The negative coefficients for the Prime Time Game indicator may arise from the inclusion of Hotel Listing Premium that is higher for prime time games according to our next analysis.

Hotel prices are unlikely to be influenced by preferences regarding team affiliations due to the diversity of their employees and operations. Instead, hotel prices proxy for the demand for accommodation. Therefore, we repeat the estimation of equation (1) using Hotel Listing Premium as the dependent variable instead of Airbnb Listing Premium.

Panel B of Table 2 reports that hotel prices are consistently higher on homecoming games but not games against rivals since the coefficient for the Rival indicator variable is occasionally significant (at the $10 \%$ level) but often insignificant. In contrast to games against rivals, homecoming is clearly stated on every college football schedule. Furthermore, Alumni returning for homecoming can participate in several events besides the football game. Therefore, homecoming is associated with a high demand for accommodation.

A positive coefficient for the Prime Time Game indicator variable signifies that hotels increase prices on important home games. As the rank variable is larger for lower quality teams, a negative coefficient for Opponent's Rank signifies a smaller listing premium on games against lower quality opponents. Conversely, a positive coefficient for the Pre-Season Top 25 Opponent indicator variable signifies that highly-ranked opposing teams increase the listing premium. This increase can be attributed to the greater willingness of fans to travel with a highly-ranked team.

### 2.2 Occupancy Rates

Our next specification has an indicator variable that equals one if a unit is booked and zero otherwise as the dependent variable

$$
\begin{align*}
&{ }_{1}^{\text {Booking }_{i, t}}= \beta_{1} \text { Airbnb Listing Premium } \\
& i, t  \tag{2}\\
&+\beta_{2} \operatorname{Rival}_{i, t} \\
&+\beta_{3} \text { Airbnb Listing Premium }_{i, t} \times \operatorname{Rival}_{i, t}+\gamma X_{t}+\epsilon_{i, t}
\end{align*}
$$

This specification supplements equation (1) with an additional independent variable defined as the interaction between the Airbnb Listing Premium and the Rival indicator variable. While a positive $\beta_{1}$ coefficient is consistent with higher listing prices reflecting greater demand for accommodation, a negative $\beta_{3}$ coefficient indicates that a high listing premium on games against rivals lowers the likelihood a unit is booked. Table 3 reports negative $\beta_{3}$ that indicate listing price increases on games against rivals reduce the likelihood that a unit is booked.

The non-negative $\beta_{2}$ coefficients are consistent with hosts not rejecting bookings by rival fans. Indeed, $95.5 \%$ of hosts activate Airbnb's Instant Book feature, which enables guests to obtain immediate confirmation of their booking without host intervention. Furthermore, guests are not required to state any college or team affiliation on their Airbnb profile. ${ }^{8}$

With regards to the control variables, the positive coefficients for Hotel Listing Premium and Hotel Occupancy indicate that the occupancy of Airbnb hosts increases with the demand for hotel accommodation. Thus, Airbnb units and hotel rooms have a common response to increases in demand. The next analysis provides more compelling evidence that the listing prices set by households are confounded by preferences regarding team affiliations.

### 2.3 Rental Incomes

Our next analysis examines the impact of unit-level listing premiums on rental incomes using the following panel regression

$$
\begin{align*}
&{\text { Rental } \text { Income }_{i, t}=} \beta_{1} \text { Airbnb Listing Premium }_{i, t}+\beta_{2} \operatorname{Rival}_{i, t} \\
&+\beta_{3} \text { Airbnb Listing Premium }  \tag{3}\\
& i, t \\
& \times \operatorname{Rival}_{i, t}+\gamma X_{t}+\epsilon_{i, t},
\end{align*}
$$

with unit fixed effects. A negative $\beta_{3}$ coefficient for the interaction variable (Airbnb Listing Premium $\times$ Rival) signifies that listing price increases on games against rivals are inversely

[^5]related to rental income. ${ }^{9}$ Appendix B contains a illustrative model that demonstrates the rental income reduction due to the influence of non-pecuniary preferences.

The positive $\beta_{1}$ coefficients in Table 4 are consistent with hosts earning higher rental income by setting higher listing prices due to greater demand. According to Table 4, the $\beta_{1}$ coefficient equals 0.752 ( $t$-statistic of 14.342) in the specification with all control variables. However, the insignificant $\beta_{2}$ coefficients and negative $\beta_{3}$ coefficients in Table 4 indicate that hosts increase listing prices on games against rivals to levels that lower their respective rental incomes. In the specification with all control variables, the $\beta_{3}$ coefficient equals - 0.284 ( $t$-statistic of -2.248). Thus, preferences regarding team affiliations confound the listing prices set by households.

The positive coefficients for the Homecoming and Pre-Season Top 25 Opponent indicator variables are consistent with greater demand, hence higher rental income. ${ }^{10}$ Overall, the listing prices set by Airbnb hosts on games against rivals cannot be attributed to higher demand for Airbnb accommodation due to the inverse relation between unit-level listing premiums and rental incomes. Instead, non-pecuniary preferences regarding team affiliations appear to confound the listing prices set by households and inhibit the maximization of their rental incomes.

## 3 Financial Constraints

Heterogeneity among Airbnb hosts and the potential for competition motivates our analysis of financial constraints. The average credit utilization score for individual zip codes provided by Experian proxies for financial constraints. The credit utilization score divides outstanding credit card debt by the total available credit, with the availability of credit reflecting household income. Zip codes where the average credit utilization score is above a college town's median credit utilization score are classified as having financially constrained hosts, while zip codes where the average credit utilization score is below this median are classified as having financially unconstrained hosts. ${ }^{11}$

A household's credit utilization score is determined by its credit card debt, not mortgage debt. Thus, financial constraints are not necessarily higher for households who utilize the tax deductibility of mortgage interest. Indeed, the average credit utilization score in a zip code is independent of the average mortgage payment. Zip-code level credit utilization scores range

[^6]from 15 to 37 , with right skewness indicating that residents in several zip codes have significantly less available credit.

Equation (1) and equation (3) are re-estimated separately for financially constrained and financially unconstrained hosts. Although the exact location of Airbnb hosts is unknown, our analysis assumes that hosts have a credit utilization score that parallels the average score near their Airbnb listing. In support of this assumption, we define professional hosts as those with more than one property listed on Airbnb. Of the 155 professional hosts in our sample, 133 have Airbnb listings in areas with the same financial constraint classification. Furthermore, professional hosts typically manage properties in the same zip code since these hosts have an average of 2.85 units in 1.34 zip codes. This geographic concentration is consistent with the need for hosts to actively manage their short-term rentals. In unreported results, the inverse relation between listing prices and rental incomes strengthens after removing the 317 observations where the financial constraints of professional hosts are ambiguous. Indeed, the misidentification of financial constraints would weaken their relations with listing prices and rental incomes.

According to Panel A and Panel B of Table 5, financially unconstrained hosts have larger listing premiums on games against rivals than financially constrained hosts. In particular, according to equation (1), the $\beta_{1}$ coefficient for financially unconstrained hosts is 31.992 ( $t$ statistic of 4.000 ) compared to 20.087 ( $t$-statistic of 4.180 ) for financially constrained hosts. This difference is significant at the $5 \%$ level. Thus, financially unconstrained hosts set listing price that are $60 \%$ larger than financially constrained hosts on games against rivals.

Moreover, in terms of rental income, Panel C of Table 5 indicates that among financially unconstrained hosts, the $\beta_{3}$ coefficient in equation (3) for the interaction between the Airbnb Listing Premium and the Rival indicator variable equals -0.502 ( $t$-statistic of -3.256 ). This coefficient is significantly more negative than its counterpart in Table 4 for the entire sample. In contrast, according to Panel D of Table 5, the $\beta_{3}$ coefficient is insignificant among financially constrained hosts. Thus, non-pecuniary preferences do not influence the listing prices of financially constrained households.

The difference in the occupancy rates of financially constrained versus financially unconstrained hosts captures competition. In unreported results, by setting lower (more competitive) listing prices on games against rivals, financially constrained hosts have a higher occupancy than financially unconstrained hosts.

The raw data provides the following in-sample averages that summarize the economic implications of financial constraints. The average rental income of financially unconstrained hosts is similar to financially constrained hosts on games against highly ranked non-rival teams; $\$ 189.42$ compared to $\$ 187.23$, respectively. Thus, financial constraints do not affect the average rental income of Airbnb hosts on games against non-rival teams. However, on games against rival
teams, the average rental income of financially unconstrained hosts declines by over $20 \%$ to $\$ 149.24$, while the average rental income of financially constrained hosts is almost unchanged at $\$ 182.56$. In summary, financially constrained hosts earn higher rental income on games against rivals than financially unconstrained hosts by setting more competitive listing prices.

## 4 Robustness Tests

Several robustness tests provided additional support for our conclusion that the lower rental incomes of Airbnb hosts on games against rivals is due to non-pecuniary preferences regarding college football team affiliations that are manifested in their listing prices.

### 4.1 Residual Listing Premium

We construct a unit-level Residual Listing premium by regressing the original Airbnb Listing Premium on the Hotel Listing Premium of each college town. This Residual Listing Premium is defined by the residual from this regression and captures listing price increases on games against rivals that are due to non-pecuniary host preferences rather than demand. Equation (1) and equation (3) are then re-estimated using the Residual Listing Premium. The results in Table 6 parallel our earlier results as the $\beta_{3}$ coefficient for the interaction between the Airbnb Listing Premium and the Rival indicator variables is negative for financially unconstrained hosts and insignificant for financially constrained hosts.

### 4.2 Homecoming

While our analysis focuses on a preference against rival fans, homecoming coincides with an influx of home team fans. ${ }^{12}$ Table 7 reports insignificant $\beta_{3}$ coefficients for the interaction variable defined as Airbnb Listing Premium $\times$ Homecoming. Therefore, we find no evidence that households set suboptimal listing prices on homecoming.

### 4.3 Placebo Test

In unreported results, we also find no evidence of this inverse relation on games against rivals in urban areas that have more than 1,000 Airbnb listings. The null result from this placebo test is consistent with college football fans exerting an insignificant impact on the demand for accommodation in urban areas.

[^7]
### 4.4 Shared Units

Fans of the home team such as Alumni also require accommodation. As members of the majority, physical separation from the local population is less important for these visiting fans. Consequently, shared units on Airbnb provide suitable accommodation for fans of the home team. Table 8 reports that listing prices for shared units are not higher on games against rivals. Thus, fans of the home team can avoid the high listing premiums for entire units on games against rivals by booking shared units.

### 4.5 Professional Hosts

Every host on Airbnb is assigned a unique identification number. In unreported results, we classify an Airbnb host as a professional if they have multiple properties listed on Airbnb. Professionals comprise $13.7 \%$ of the hosts and manage $25.5 \%$ of the listings in our sample. Professional hosts are as likely to be financially constrained as financially unconstrained, and $94.2 \%$ adopt the Instant Book feature. Thus, professional hosts and non-professional hosts have similar characteristics. However, the inverse relation between unit-level listing premiums and rental incomes is limited to non professional financially unconstrained hosts that manage $40 \%$ of the entire Airbnb units in our sample.

### 4.6 Stadium Incidents

We compile data on stadium incidents defined as arrests and ejections to verify the classification of rival teams. The identification of rival teams is confirmed by a higher number of stadium incidents (arrests and ejections) on games against rivals according to Table 9. ${ }^{13}$ Specifically, the positive coefficient of 16.489 ( $t$-statistic of 2.808 ) for the Rival indicator variable in the full specification indicates a higher number of incidents on games against rivals. In contrast, homecoming games are associated with fewer stadium incidents due to the negative coefficient of -5.376 ( $t$-statistic of -2.126). The Prime Time Game indicator variable has positive coefficients that are consistent with more important college football games eliciting stronger fan emotions. Similarly, higher ranked opponents lead to more stadium incidents as the Pre-Season Top 25 Opponent indicator variable has positive coefficients while the coefficients for Opponent's Rank are negative. These coefficients are consistent with fans of higher ranked teams being more willing to travel with the visiting team, which increases the likelihood of interactions between opposing fans at the stadium.

[^8]
### 4.7 Expected Damage

Although several game and visiting team characteristics influence the number of stadium incidents, Table 2 reports that these characteristics do not increase Airbnb listing prices or hotel prices. Therefore, incidents at the stadium where opposing fans interact do not imply higher expected damage to hotel rooms or entire units on Airbnb that physically separate visitors from the local population.

Furthermore, the inverse relation between unit-level listing premiums and rental incomes cannot be attributed to a higher cost of providing accommodation to rival fans. Besides the insurance provided by Airbnb to hosts, unreported results confirm that Airbnb hosts do not increase their required damage deposits on games against rivals. Furthermore, hotel rooms are also susceptible to damage but hotel prices do not increase significantly on rival games. In addition to retaining the credit card information of guests, Airbnb hosts rate guests. This rating provides a further incentive for guests to act responsibly. ${ }^{14}$ Moreover, variation in listing prices attributable to host characteristics such as financial constraints is unlikely to explain the likelihood that a unit is damaged. Finally, Airbnb allows hosts to block their unit from being booked on specific dates. In unreported results, the propensity of hosts to block their unit is not higher on games against rivals. Moreover, units booked on rivals games are not more likely to be subsequently blocked by the host during the following week. Consequently, it does not appear that units booked by rival fans are more likely to require repairs.

### 4.8 Taste-based versus Statistical Discrimination

Our empirical results support taste-based discrimination by Airbnb hosts against rival fans rather than statistical discrimination. In the classic expected utility framework, financial decisions result from preferences and probabilities. Our empirical results are consistent with tastebased discrimination, which operates through the preferences channel (Becker, 1957). This channel implies that hosts accept lower rental income to avoid accommodating fans of the rival football team. Alternatively, statistical discrimination (Arrow, 1973; Phelps, 1972) operates through the probability channel. In contrast to our empirical results, this channel has households setting higher listing prices on games against rivals as compensation for the higher likelihood of incurring damage.

[^9]
## 5 Conclusion

We study the impact of college football rivalries on the financial decisions of Airbnb hosts. We report that non-pecuniary preferences regarding team affiliations confound the listing prices set by hosts. Specifically, listing price increases on games against rivals lead to lower rental income. This inverse relation between listing price increases and rental incomes is concentrated in financially unconstrained hosts. Thus, financial constraints appear to mitigate non-pecuniary household preferences that induce suboptimal pricing decisions.

## Appendix B: Illustrative Model

Let $P$ denote the listing price set by a household. In the absence of non-pecuniary preferences, the host sets the listing price to maximize

$$
\begin{equation*}
\text { Rental Income }=\text { Listing Price } \times \text { Probability (Occupancy } \mid \text { Listing Price) } . \tag{4}
\end{equation*}
$$

This maximization is equivalent to setting a listing price that maximizes

$$
\begin{equation*}
P \times[1-\alpha P] \tag{5}
\end{equation*}
$$

provided Occupancy is determined by the function Probability (Occupancy|Listing Price) $=$ $1-\alpha P$ where $\alpha>0$ determines the demand curve for accommodation. In our empirical estimation, variation in $\alpha$ across different home games is captured by hotel prices and game characteristics such as team rankings.

Rental income in equation (5) is maximized at $\frac{1}{4 \alpha}$ by setting the listing price to $P=\frac{1}{2 \alpha}$. Thus, rental income is half the listing price as host occupancy equals $50 \%$.

To incorporate a non-pecuniary preference regarding team affiliations, let $P_{R}=P+D$ denote the host's listing price on games against rival visiting teams. $D \geq 0$ quantifies the price premium a host requires to overcome their non-pecuniary preference against rival fans. $D$ differs from $\alpha$ along two dimensions. First, our empirical implementation has $D$ only being non-zero on games against rivals, while $\alpha>0$ varies across different home game. Second, in contrast to $\alpha, D$ can vary across hosts. Overall, there is a one-to-one correspondence between a host's non-pecuniary preference and the host's listing price after accounting for the demand for accommodation.

Rental income of $\frac{1}{4 \alpha}-\alpha D^{2}$ on games against rivals is reduced by the host's non-pecuniary preference, which increases their listing price by $D$. For completeness, the constraint $D \leq \frac{1}{2 \alpha}$ prevents the host's occupancy, and rental income, from being negative by preventing the host from setting a listing price that is twice the amount justified by demand.
Appendix C: Variable Description

| Variable | Description |
| :--- | :--- |
| Rival | An indicator variable that equals one if the home game is against a rival opponent, and zero otherwise. |
| Listing Premium | A unit's listing price on a specific game minus the average listing price for all home games in the same football season. |
| Prime Time Game | An indicator variable that equals one if the home game occurs at 5pm or later, and zero otherwise. |
| Homecoming | An indicator variable that equals one if the home game coincides with the homecoming weekend, and zero otherwise. |
| Opponent's Rank | The visiting team's ranking prior to the game. If the opponent is unranked, this rank is set to 50. |
| Home Team's Rank | The home team's ranking prior to the game. If the home team is unranked, this rank is set to 50. |
| Pre-Season Top 25 Opponent | An indicator variable that equals one if the opponent was ranked a top 25 team before the start of the season, and zero otherwise. |
|  | Pre-Season ranking is obtained from the AP Poll. |
| Number of Units | The number of entire units listed on Airbnb in a college town. |
| Hotel Listing Premium | The average hotel price on a specific game minus the average hotel price across all home games in the same football season. |
| Financially Unconstrained | Units listed in a zip code whose average credit utilization score is below the median score of all zip codes in the college town. |
| Financially Constrained | Units listed in a zip code whose average credit utilization score is above the median score of all zip codes in the college town. |
| Professional Hosts | Professional Hosts have more than one property listed on Airbnb. |

## Table 3: Airbnb Occupancy Rates

This table reports the coefficients from the unit fixed effects panel regression in Equation (2). The dependent variable, occupancy, is an indicator variable equal to one if a unit is booked on Airbnb, and zero if the unit is not booked. The sample consists of entire units on Airbnb located in college towns. Airbnb Listing Premium is computed at the unit level as the average listing price on a specific game minus the average listing price for all home games during the season. Rival is an indicator variable that equals one if the home game is against a rival opponent, and zero otherwise. Opponent's Rank is the incoming rank of the opponent prior to the start of the game, and equals 50 if the team is unranked. Home Team's Rank is the rank of the home team prior to the start of the game, and equals 50 if the team is unranked. Prime Time Game is an indicator variable equal to one if the game occurs at 5pm or later, and zero otherwise. Homecoming is an indicator variable equal to one if the game takes place on the homecoming weekend, and zero otherwise. Hotel Listing Premium is computed at the city level as the average hotel price on a specific game minus the average hotel price for all home games during the season. Distance refers to the number of miles separating the location of the home team and the visiting team. All continuous variables are standardized. $t$-statistics are reported in parentheses. Standard errors are clustered at the team level. ${ }^{*},{ }^{* *}$, and ${ }^{* * *}$ indicate significance at the $10 \%, 5 \%$, and $1 \%$ levels, respectively.

|  | Occupancy of Airbnb Units |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 4: Airbnb Rental Incomes
This table reports the coefficients from the unit fixed effects panel regression in Equation (3) where the rental income of Airbnb units is the dependent variable. Airbnb Listing Premium is computed at the unit level as the listing price on a specific game minus the average listing price for all home games during the season. Rival is an indicator variable that equals one if the home game is against a rival opponent, and zero otherwise. Opponent's Rank is the incoming rank of the opponent prior to the start of the game, and equals 50 if the team is unranked. Home Team's Rank is the rank of

 price on a specific game minus the average hotel price for all home games during the season. Distance refers to the number of miles separating the location of the home team and the visiting team. $t$-statistics are reported in parentheses. Standard errors are clustered at the team level. ${ }^{*},{ }^{* *}$, and ${ }^{* * *}$ indicate significance at the $10 \%, 5 \%$, and $1 \%$ levels, respectively.

Table 5: Financial Constraints, Listing Premiums, and Rental Incomes
Panel A and Panel B report the coefficients from the unit fixed effects panel regression in Equation (1), while Panel B and Panel C report the coefficients from the unit fixed effects panel regression in Equation (3). A low credit utilization score corresponds with financially unconstrained hosts, while a high credit utilization score corresponds with financially constrained hosts. Airbnb Listing
 the home game is against a rival opponent, and zero otherwise. Opponent's Rank is the incoming rank of the opponent prior to the start of the game, and equals 50 if the team is unranked. Home or later, and zero otherwise. Pre-Season Top 25 Opponent is an indicator variable equal to one if the incoming opponent was ranked a top 25 team on the Associated Press Poll at the start of the season, and zero otherwise. Homecoming is an indicator variable equal to one if the game takes place on the homecoming weekend, and zero otherwise. Hotel Listing Premium is computed at the city level as the average hotel price on a specific game minus the average hotel price for all home games during the season. Distance refers to the number of miles separating the location of the home
team and the visiting team. $t$-statistics are reported in parentheses. Standard errors are clustered at the team level. $*$, **, and $* * *$ indicate significance at the $10 \%, 5 \%$, and $1 \%$ levels, respectively.

Panel A: Airbnb Listing Premiums of Financially Unconstrained Hosts

## Table 6: Residual Listing Premiums

This table reports the coefficients from the unit fixed effects panel regression where the rental income of Airbnb units is the dependent variable. Residual Listing Premium is computed by regressing the Airbnb Listing Premium onto the Hotel Listing Premium. Airbnb Listing Premium is computed at the unit level as the listing price on a specific game minus the average listing price for all home games during the season. Hotel Listing Premium is computed at the city level as the average hotel price on a specific minus the average hotel price for all home games during the season. A low credit utilization score corresponds with financially unconstrained hosts in Panel A, while a high credit utilization score corresponds with financially constrained hosts in Panel B. Rival is an indicator variable that equals one if the home game is against a rival opponent, and zero otherwise. Opponent's Rank is the incoming rank of the opponent prior to the start of the game, and equals 50 if the team is unranked. Home Team's Rank is the rank of the home team prior to the start of the game, and equals 50 if the team is unranked. Prime Time Game is an indicator variable equal to one if the game occurs at 5 pm or later, and zero otherwise. Pre-Season Top 25 Opponent is an indicator variable equal to one if the incoming opponent was ranked a top 25 team on the Associated Press Poll at the start of the season, and zero otherwise. Homecoming is an indicator variable equal to one if the game takes place on the homecoming weekend, and zero otherwise. Distance refers to the number of miles separating the location of the home team and the visiting team. $t$-statistics are reported in parentheses. Standard errors are clustered at the team level. ${ }^{*},^{* *}$, and ${ }^{* * *}$ indicate significance at the $10 \%, 5 \%$, and $1 \%$ levels, respectively.

Table 7: Homecoming Games
This table reports the coefficients from a unit fixed effects panel regression where the rental income of Airbnb units is the dependent variable. Airbnb Listing Premium is computed at the unit level as the listing price on a specific game minus the average listing price for all home games during the season. Homecoming is an indicator variable equal to one if the game takes place on the

 otherwise. Hotel Listing Premium is computed at the city level as the average hotel price on a specific game minus the average hotel price for all home games during the season. Distance refers to the number of miles separating the location of the home team and the visiting team. $t$-statistics are reported in parentheses. Standard errors are clustered at the team level. *, **, and ${ }^{* * *}$ indicate significance at the $10 \%, 5 \%$, and $1 \%$ levels, respectively.

Table 8: Shared Units on Airbnb
This table reports the coefficients from the unit fixed effects panel regression for shared units listed on Airbnb whose listing price changed at least once during the football season. For shared units, Airbnb Listing Premium is computed at the unit level as the listing price on a specific game minus the average listing price for all home games during the season. Rival is an indicator variable that equals one if the home game is against a rival opponent, and zero otherwise. Homecoming is an indicator variable equal to one if the game takes place on the homecoming weekend, and zero otherwise. Opponent's Rank is the incoming rank of the opponent prior to the start of the game, and equals 50 if the team is unranked. Home Team's Rank is the rank of the home team prior to the start of the game, and equals 50 if the team is unranked. Pre-Season Top 25 Opponent is an indicator variable equal to one if the incoming opponent was ranked a top 25 team on the Associated Press Poll at the start of the season, and zero otherwise. Prime Time Game is an indicator variable equal to one if the game occurs at 5 pm or later, and zero otherwise. Hotel Listing Premium is computed at the city level as the average hotel price on a specific game minus the average hotel price for all home games during the season. Distance refers to the number of miles separating the location of the home team and the visiting team. $t$-statistics are reported in parentheses. Standard errors are clustered at the team level. ${ }^{*}$, **, and ${ }^{* * *}$ indicate significance at the $10 \%, 5 \%$, and $1 \%$ levels, respectively.

| Rival | Airbnb Listing Premium |  |  |  |  |  |  |

Table 9: Stadium Incidents
This table reports the coefficients from a team fixed effects regression explaining the number of stadium incidents, defined as the sum of stadium arrests and ejections for each home game. Rival is an indicator variable that equals one if the home game is against a rival opponent, and zero otherwise. Homecoming is an indicator variable equal to one if the game takes place on the homecoming weekend, and zero otherwise. Prime Time Game is an indicator variable equal to one if the game occurs at 5pm or later, and zero otherwise. Opponent's Rank is the incoming rank of the opponent prior to the start of the game, and equals 50 if the team is unranked. Home Team's Rank is the rank of the home team prior to the start of the game, and equals 50 if the team is unranked. Pre-Season Top 25 Opponent is an indicator variable equal to one if the incoming opponent was ranked a top 25 team on the Associated Press Poll at the start of the season, and zero otherwise. Distance refers to the number of miles separating the location of the home team and the visiting team. $t$-statistics are reported in parentheses. Standard errors are clustered at the team level. *, ${ }^{* *}$, and ${ }^{* * *}$ indicate significance at the $10 \%, 5 \%$, and $1 \%$ levels, respectively.

## Figure 1: Difference in Listing Premium: Airbnb - Hotels

This figure illustrates the difference in the listing premium between Airbnb units and hotel rooms. The Airbnb listing premium is computed at the unit level as the listing price on a specific game, such as homecoming, minus the unit's average listing price across all home games in the same season. The hotel listing premium is computed at the college level as the average hotel price on a specific game minus the average hotel price across all home games in the same season.

## Figure 2: Days of the Week

Panel A of this figure illustrates the average occupancy rate of Airbnb units and hotels on each weekday within our sample of college towns. Panel B reports the associated rental income (revenue) of Airbnb units and hotels on each weekday. This figure provides evidence that weekends are critically important to the rental incomes of Airbnb hosts.

Panel A. Average Occupancy by Weekday

Panel B. Revenue (\%) by Weekday

[^1]:    ${ }^{1}$ The Pricewaterhouse Coopers report can be accessed at: http://www.pwc.com/us/en/technology/publications/ assets/pwc-consumer-intelligence-series-the-sharing-economy.pdf
    ${ }^{2}$ Besides generating income, online tools have the ability to impact the financial decisions of households by providing information. Levi (2014) demonstrates the effectiveness of an online tool at decreasing consumption by providing an easy-to-interpret summary of a household's net worth.

[^2]:    ${ }^{3}$ We verify that hosts with multiple Airbnb units concentrate their units in the same zip code. This geographic concentration is consistent with short-term accommodation rentals requiring frequent monitoring.
    ${ }^{4}$ This interpretation is more likely than financially constrained households having weaker preferences regarding college football affiliations.
    ${ }^{5}$ Entire units are as likely to have a financially constrained host as a financially unconstrained host.

[^3]:    ${ }^{6}$ The website www.airbnb.com/guarantee provides details of the insurance provided by Airbnb to its hosts.

[^4]:    ${ }^{7}$ A lottery preference cannot explain the variation in listing prices on different home games. The lottery preference predicts that hosts accept the low probability of obtaining a booking by setting a high listing price on every game.

[^5]:    ${ }^{8}$ Edelman, Luca, and Svirsky (2016) create fake guest Airbnb accounts and find that hosts are more likely to reject prospective guests who are minorities. However, their empirical design does not examine the price mechanism that is the basis of our study.

[^6]:    ${ }^{9}$ The results are robust to the inclusion of both squared and cubed listing premiums that capture nonlinearities in the income function.
    ${ }^{10}$ The average number of units listed on Airbnb has a positive relation with both listing prices and rental incomes at the unit level. As entire units on Airbnb are a substitute for hotel rooms, more Airbnb units in a college town may signify that the number of hotel rooms is inadequate.
    ${ }^{11}$ Results are similar if the median credit utilization score across all zip codes is used to distinguish financially constrained from financially unconstrained.

[^7]:    ${ }^{12}$ According to Panel B of Table 2, hotel prices increase on homecoming, with the inclusion of hotel prices as a control variable eliminating the impact of homecoming on Airbnb prices in Panel A.

[^8]:    ${ }^{13}$ Rees and Schnepel (2009) report increased crime surrounding the location of college football games, while Card and Dahl (2011) link unexpected losses in the National Football League to increased domestic violence.

[^9]:    ${ }^{14}$ Guests also rate their host. However, hosts typically have many more ratings than guests. Furthermore, if rival fans were more likely to assign a poor review to hosts as a result of their mutual dislike, all hosts on games against rivals would be susceptible to a bad review. Thus, a host's competitiveness relative to their peers is unchanged.

[^10]:    Table 2: Listing Premiums
     average listing price for all home games during the season. Panel B reports the coefficients from the team fixed effects panel regression that has Hotel Listing Premium as the dependent variable.
     opponent prior to the start of the game, and equals 50 if the team is unranked. Home Team's Rank is the rank of the home team prior to the start of the game, and equals 50 if the team is unranked.
     opponent was ranked a top 25 team on the Associated Press Poll at the start of the season, and zero otherwise. Homecoming is an indicator variable equal to one if the game takes place on the homecoming weekend, and zero otherwise. Distance refers to the number of miles separating the location of the home team and the visiting team. $t$-statistics are reported in parentheses. Standard errors are clustered at the team level. ${ }^{*},{ }^{* *}$, and ${ }^{* * *}$ indicate significance at the $10 \%, 5 \%$, and $1 \%$ levels, respectively.
